

ABSTRACT

A wireless method and apparatus for transmitting signal, for example, from a source, to headphones or speakers, while allowing relatively unrestricted

5 range of movement/placement for the headphones or speakers. An infrared transmitter diverges its signal by passing the signal through a concave lens.

The signal is processed to bounce off of objects, such as, walls, ceilings and

floors before reaching the receiver on the headphones/speakers. The receiver has a convex lens affixed to it, so as to converge the transmitted signal. The

10 signal is polarized so that ambient light is filtered.
